Terahertz Spectroscopy on Graphene-Polymer Nanocomposites

By: Rabi Shrestha, Anton Koroliov PhD and Roman Sobolewski PhD
Department of Electrical and Computer Engineering, University of Rochester

**Introduction**

Terahertz time domain spectroscopy (THz - TDS) is a non-destructive form of spectroscopy, which utilizes THz waves to measure the electrical and optical properties of objects with sub-picosecond resolution. The advantage of this method compared to conventional spectroscopy, is that it measures the amplitude and phase of the THz electromagnetic field. This allows for the calculation of such parameters as index of refraction and absorption coefficient, electric permittivity and conductivity. This method is being in the lab, to characterize the properties of graphene - polymer samples.

**Setup**

The THz TDS setup that was used is shown in Figure 1. A tunable Ti: Sapphire laser, with a wavelength of 800 nm, was used to excite the photoconductive GaAs emitter which generates THz radiation. A similarly developed photoconductive GaAs detector was utilized to detect the THz radiation (Figure 2). A delay stage was used to measure cross-sections of the THz pulse, to capture a time domain signal (Figure 3A). The measurements were conducted in a nitrogen environment to eliminate the water vapor absorption.

**Measurement Results**

The THz pulses [A], Spectrum of the THz pulses [B], Absorption Coefficient [C], Transmission through sample [D] were tested. THz pulses [A], Spectrum of the THz pulses [B], Absorption Coefficient [C], Transmission through sample [D] were tested.

**Conclusions**

- A 0.9 mm thick graphene-polymer sample with graphene composition of 0.05% or 1% were tested.
- The data collected from these samples consistently showed an increase in absorption and decrease in transmission compared to the undoped polymer.
- The dielectric function and electric conductivity of graphene-polymer sample was calculated.
- Drude-Lorentz model (Figure 5) fits the permittivity and conductivity data the best (Figure 6).
- The phonon frequencies, plasma frequencies, and scattering rates (as seen in figure 6) were extracted from the fit data.

**Calculated Results**

\[ \varepsilon_{\text{particle}} = \varepsilon_{\infty} + \frac{\varepsilon_0 \omega_p^2}{\omega^2 - i\Gamma \omega} + \sum \frac{\varepsilon_0 \omega_p^2}{(\omega^2 - \omega_0^2)^2 + i\gamma \omega} \]

**Acknowledgement**

I would like to thank Dr. Anton Koroliov for letting me work on his project and Dr. Roman Sobolewski for the opportunity to work in his lab over the summer and guiding me on this project. I would also like to thank the Xerox Fellows program for funding my research. This research was performed at the Ultrafast Quantum Phenomena Laboratory at the Laboratory of Laser Energetics.
